# Chapter 6

# Gases

1

A Gas

- · Uniformly fills any container.
- Easily compressed.
- Mixes completely with any other gas.
- Exerts pressure on its surroundings.

© 2020 Amo Papaz

3

But first ... let's understand how pressure is generated in dense materials (liquids and solids): by an external force

The weight of liquid "sitting" above an area generates hydrostatic pressure, which is literally the weight of the liquid column divided by the area on which it "sits"

Weight Weight 5

- P=0.5 atm

P= 1.0 atm-

Why study gases?

- To understand an important part of real world phenomena.
- A lot of industrial chemistry involves gases.
- They are the simplest of the three phases to understand and quantitatively model (i.e. predict) their behavior
- A good case study to see some scientific concepts and principles in action

© 2020 Arno Papazyan

2

#### Pressure

Pressure = 
$$\frac{\text{force}}{\text{area}}$$

SI units = Newton/meter<sup>2</sup> = 1 Pascal (symbol: Pa)

1 standard atmosphere (symbol: atm) = 101,325 Pa

1 standard atmosphere = 1 atm = 760 mm Hg = 760 torr

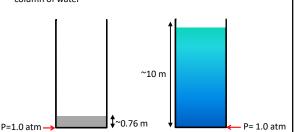

The "normal" atmospheric pressure is approximately equal to a "standard atmosphere" or simply "atmosphere"

© 2020 Arno Papazya

4

Dense liquids require less height to generate the same pressure as a less dense liquid

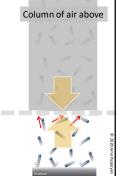

- Mercury is 13.6 denser than water
- 760 mm (0.760 m) generates the same hydrostatic pressure as ~10 m column of water

Normally, we can ignore the effect of gravity on the behavior of a human-scale sample of gas

But a planet-wide atmosphere is of course held in place and "compressed" to a pressure by gravity

Air around us is holding up the column of air above us in the atmosphere by applying a force in the opposite direction

7

So the air at the surface of the earth owes its pressure to the weight of the "column of air" sitting on top of any given point But ...

- What if we take a sample of the air and put it in a sealed box without altering its pressure?
- Will it have little or no pressure because there is no "column of air" above it?

No, it will generate the same pressure

 It will retain its pressure because the pressure of a gas is generated by its particles bouncing against the walls of its container.

© 2020 Arno Panazuan

8

ressur

We will **only** deal with human-scale samples where gravity is not important.

The gas will be contained within container walls.

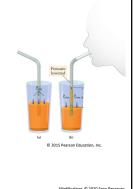

© 2020 Amo Papazy

9

Heard of barometers? Let's first understand straws

(a) The pressure inside and outside the straw is the same, so the liquid levels inside and outside the straw are the same.

(b) When we suck on the straw, the pressure inside the straw is lowered. The greater pressure on the surface of the liquid outside the straw pushes the liquid up the straw.

10

Note:

Patm | Patm | Note:

Pressure is directionless

If you apply it to a fluid, it is transmitted in all directions

Atmosphere pressing "down" on the liquid surface translates to liquid pressing up into the straw

Even if you formed a perfect vacuum with a pump, atmospheric pressure could only push orange soda to a total height of about 10 m.

 A column of water (or soda) 10.3 m high exerts the same pressure as the gas molecules in the atmosphere.

Heard of barometers? Let's first understand straws

The pressure exerted by the atmosphere is equal to the pressure exerted by a 10.3-m column of water

Vacuum

Pressure exerted by 10.3-m column of orange soda: 14.7 pounds per square inch

gas molecules in the atmosphere.

10.3 m

Modifications 0 2020 Amo Paparyan

11 12

 We could measure the height of the water column to measure the atmospheric pressure

- If the atmospheric pressure is holding up 10.342 meters, we could even make it a unit and say "atmospheric pressure is 10.342 meters water"
- But it would be a huge, unwieldy instrument
- A much denser liquid would have much shorter height: Mercury!

The pressure exerted by the atmosphere is equal to the pressure exerted by a 10.3-m column of water

Vacuum

Pressure exerted by 10.3-m column of orange soda: 14.7 pounds per square inch

Pressure exerted by our atmosphere: 14.7 pounds per square inch

Heard of barometers? Let's first understand stra

13

Barometer

Device used to measure atmospheric pressure

Mercury flows out of the tube until the pressure of the column of mercury standing on the surface of the mercury in the dish is equal to the pressure of the air on the rest of the surface of the mercury in the dish.

Weight of the mercury column is balanced by the force due to air pressure

The width of the column doesn't matter. The wider it is, the heavier the column, but also the larger the force due to air

14

pressure (F=P·A)

#### Pressure unit conversions: An Example

The pressure of a gas is measured as 2.5 atm. Represent this pressure in both torr and pascals.

$$(2.5 \text{ ptm}) \times \left(\frac{760 \text{ torr}}{1 \text{ ptm}}\right) = 1.9 \times 10^3 \text{ torr}$$
  
 $(2.5 \text{ ptm}) \times \left(\frac{101,325 \text{ Pa}}{1 \text{ ptm}}\right) = 2.5 \times 10^5 \text{ Pa}$ 

2020 Amo Papazyan

15

Gas Laws

Gas laws are mathematical relationships between the properties of a gas.

The 4 properties (variables) that define the state of a gas are:

Pressure (P)

Volume (V)

Temperature (T) ← Must be in Kelvins!

Cannot be in °C or °F!

Number of moles (n)

16

# Liquid Nitrogen and a Balloon

Very cold: -320°F (-196°C)

What happened to the gas in the balloon?

Liquid Nitrogen and a Balloon

 Lower temperature was accompanied by a lower volume of the gas in the balloon.

2020 Arno Papazy

as Lav

#### Liquid Nitrogen and a Balloon

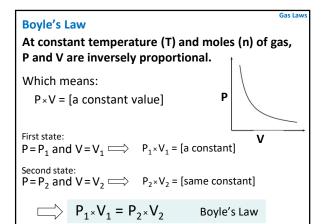

"Lower temperature was accompanied by a lower volume of the gas in the balloon" is an **observation** (a fact).

It does not yet rise to the level of a "law"

But gas laws can be deduced from observations like these

2020 Amo Papazyan

19

20

#### **Example:**

A sample of helium gas occupies 12.4 L at 23°C and 0.956 atm. What volume will it occupy at 1.20 atm assuming that the temperature stays constant?

We recognize this as a "Boyle's Law" problem: Temperature (T) is constant Amount of gas (n) is constant ("a sample of gas") Pressure (P) and volume (V) are changing

 $P_1 V_1 = P_2 V_2$ 0.956 atm 12.4 L 1.20 atm

 $(0.956)(12.4) = (1.20) V_2 \implies V_2 = 9.88 L$ 

020 Arno Papazya

21

Charles's Law

At constant pressure (P) and moles (n) of gas,

V and T are directly proportional

Which means:  $\frac{V}{T} = [a \text{ constant value}]$ First state:  $T = T_1 \text{ and } V = V_1 \Longrightarrow \frac{V_1}{T_1} = [a \text{ constant}]$ Second state:  $T = T_2 \text{ and } V = V_2 \Longrightarrow \frac{V_2}{T_2} = [same \text{ constant}]$   $\frac{V_1}{T_1} = \frac{V_2}{T_2}$ Charles's Law

22

In gas laws, temperature unit must be Kelvin.

You cannot use °C or °F!

Using use °C or °F would bring addition or subtraction into the equations, and the simple, direct or inverse proportionality relationships would be lost.

The gas laws that we learn would not apply if we use the wrong temperature unit!

**Example:** 

Gas La

A balloon containing 1.30 L of air at 24.7°C is placed into a beaker containing liquid nitrogen at 77.0 kelvins. What will the **volume** of the sample of air become?

We recognize this as a "Charles's Law" problem:

Pressure (P) is constant (for a balloon P = P<sub>room</sub>)

Amount of gas (n) is constant ("the sample of air")

Temperature (T) and volume (V) are changing

1.30 L  $V_1 = V_2$  ? (24.7 + 273.15) K  $T_1 = T_2$  77 K

 $(1.30) (77.0) / (24.7 + 273.15) = V_2$   $\Longrightarrow$   $V_2 = 0.336 L$ 

2020 Arno Papazy

23

#### Avogadro's Law

At constant temperature (T) and pressure (P)

V and n are directly proportional

Which means:

$$\frac{V}{n}$$
 = [a constant value]

First state:  

$$V = V_1$$
 and  $n = n_1$   $\longrightarrow$   $\frac{V_1}{n_1} = [a constant]$ 

Second state:

Second state:  

$$V = V_2$$
 and  $n = n_2$   $\Longrightarrow \frac{V_2}{n_2} = [same constant]$ 

$$\frac{V_1}{n_1} = \frac{V_2}{n_2}$$
 Avogadro's Law

25

#### **Example:**

If 2.45 mol of argon gas occupies a volume of 89.0 L, what volume will 2.10 mol of argon\* occupy under the same conditions of temperature and pressure?

We recognize this as an "Avogadro's Law" problem: Pressure (P) and temperature (T) are constant Number of moles (n) and volume (V) are changed

89.0 L 
$$\frac{V_1}{n_1} = \frac{V_2}{n_2}$$
? 2.10 mol

 $(89.0) (2.10) / (2.45) = V_2$   $\Longrightarrow$   $V_2 = 76.3 L$ 

\* It wouldn't matter if the second state involved another gas, say, oxygen. What matters is the number of moles of whatever gas.

26

#### Combined gas law

We can combine Boyle's law and Charles' Law into a "combined" gas law:

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2}$$
 Combined Gas Law

satisfies both laws when we hold constant the appropriate pairs of variables

27

Other "combined" gas laws can be derived

Boyle's Law & Avogadro's Law together give:

$$\frac{P_1 V_1}{n_1} = \frac{P_2 V_2}{n_2}$$

Charles' Law & Avogadro's Law together give:

$$\frac{T_1 \, n_1}{V_1} = \frac{T_2 \, n_2}{V_2}$$

These just demonstrate the idea of combining laws. No need to memorize them.

28

We can combine Boyle's Law, Charles's Law, and Avogadro's Law to obtain:

$$\frac{P_1 V_1}{n_1 T_1} = \frac{P_2 V_2}{n_2 T_2} \implies \frac{P V}{n T} = constant$$

Let's call it the "Gas Constant", and give it the symbol R

$$\implies \frac{PV}{nT} = R \implies PV = nRT \quad \text{Ideal Gas Law}$$

The units and value of R depends on the units of P, V, T, n When the units are atm, L, K, mol, then

R = 0.08206 L atm/(mol K)

PV = nRT Ideal Gas Law

It's called the "Ideal Gas Law" because it corresponds to an "idealized" version of actual gases:

- Volume of the gas particles are negligible (zero)
- No attractive forces between gas particles

The second approximation means:

- The particles are unaware of one another's existence
- Different gases mixed together are unaware of and undisturbed by one another

29

Other gas laws can be easily derived from PV=nRT Red symbols can vary Blue symbols are constant

PV = nRTn, T constant PV = constant  $P_1V_1 = P_2V_2$ 

Boyle's Law

 $\frac{V}{T} = \frac{nR}{P}$ n, P constant

Charles' Law

P, V constant

nT = constant  $n_1T_1 = n_2T_2$ 

¥ = constant

Un-named

31

32

Gay-Lussac's Law

How about a law relating P and n?

Deciding which law to use

1 variable constant, 3 variables changing

what's held constant is not n.

> If P, V, T are all changing, but n is constant (a

common case), use the usual "combined gas law".

> You can also derive other "combined" gas laws if

Can you derive it from the Ideal Gas

There are only 4 variables to consider.

> and one equation (Ideal Gas Law) tying them together.

Recap: Gas laws and variables that are held constant

If we hold 3 variables constant

The 4<sup>th</sup> one is determined from the other three.

One equation, one unknown. You can solve for it.

If we hold **2** variables constant

The other 2 vary according to a "named law"

- ➤ Boyle's Law, Charles's Law, etc.
- they are either directly or inversely proportional

If we hold 1 variable constant

We get a "combined" gas law that ties together the other 3 variables

33

Deciding which law to use

#### 2 variables constant, 2 variables changing

- > Use "Named" laws like Boyle's Law, Charles Law, etc.
- > Sometimes you need to derive an unnamed law from the ideal gas law

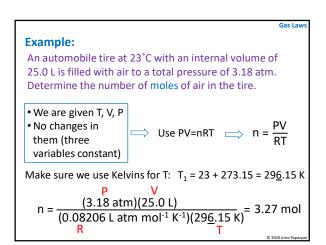

34

Deciding which law to use

#### 3 variables constant

- > The remaining 4<sup>th</sup> variable is found from the ideal gas law PV = nRT
- > "3 variables constant" means the 4<sup>th</sup> one is also constant, but we just need to determine its value
- There is **no change** in <u>any</u> of the 4 variables
  - > At least the relevant part of the problem won't involve a change in the state of the gas

35 36

Example:

What is the pressure in a 304.0 L tank that contains 5.670 kg of helium at 25°C?

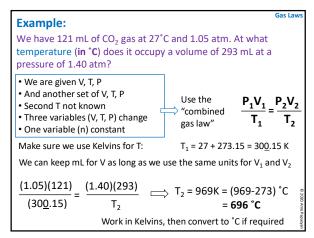

• We are given V, mass (which can give n), T
• No changes in them (Three variables constant)

Make sure we use Kelvins for T:  $T_1 = 25 + 273.15 = 29\underline{8}.15 \text{ K}$   $n = 5.670 \text{ kg} \frac{10^3 \text{ g}}{1 \text{ kg}} \frac{1 \text{ mol}}{4.0026 \text{ g}} = 141\underline{6}.4 \text{ mol}$   $P = \frac{1416.4 \text{ mol}(0.08206 \text{ L atm mol}^{-1} \text{ K}^{-1})(29\underline{8}.15 \text{ K})}{(304.0 \text{ L})} = 114 \text{ atm}$ 

38

40

37

Concept Practice:
You are holding two balloons of the same volume. One contains helium, and one contains hydrogen. Answer the upcoming questions as "different" or "the same" and explain.

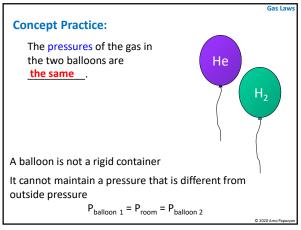

A balloon is not a rigid container It cannot maintain a pressure different from outside P

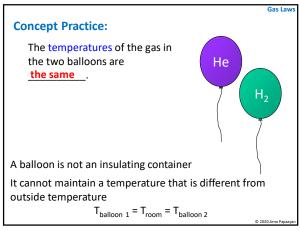

P<sub>balloon 1</sub> = P<sub>room</sub> = P<sub>balloon 2</sub>

A balloon is not an insulating container It cannot maintain a temperature different from outside T

T<sub>balloon 1</sub> = T<sub>room</sub> = T<sub>balloon 2</sub>

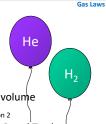

39

#### **Concept Practice:**

The numbers of moles of the gas in the two balloons are the same.

• The question said they had the same volume  $V_{balloon\ 1} = V_{balloon\ 2}$ 

- We deduced that they have the same P and T values
- If 3 of the 4 variables are fixed, the 4<sup>th</sup> one is also constant.
   Because it is determined from the other 3 by PV = nRT

$$n = \frac{PV}{RT}$$

A given set of P, V, T values dictates a unique value for  $\boldsymbol{n}$ 

43

#### **Concept Practice:**

The densities of the gas in the two balloons are different .

- A mole of He has a different mass than a mole of H<sub>2</sub>
- Same number of moles of two different gases have different masses
- The one with greater molar mass has more mass for a given number of moles ( $n_{He} = n_{H2}$ ) mass = (moles)×(molar mass) Since m.m.(He) = 4.00 g/mol; m.m. (H<sub>2</sub>) = 2.02 g/mol
- Helium has almost double the mass of H<sub>2</sub> for a given n
- Remember: density = mass/volume

© 2020 Arno Panazya

44

#### Molar Volume of an Ideal Gas

By convention, a "standard temperature and pressure" (STP) has been defined as:

0°C and 1 atm

#### At STP, 1 mole of an ideal gas has a volume of 22.42 L

- It is a convenient fact to memorize
- But we can readily find it by using the ideal gas law:

$$V = \frac{nRT}{P} = \frac{(1.000 \text{ prof})(0.08206 \text{ L} \cdot \text{atm}) \text{K} \cdot \text{prof})(273.2 \text{K})}{1.000 \text{ atm}} = 22.42 \text{ L}$$

D 2020 Amo Papa:

45

47

#### Molar Volume of an Ideal Ga

- Knowing that 1 mole of gas has 22.42 L of volume at 273.15 K and 1 atm gives us the same information as knowing the gas constant R.
- In fact, to measure R experimentally, one would measure the V for a given n, P, T.
- STP is just one set of n, P, T, V values, always constrained only by the value of R.

PV = nRT

**Example:** 

$$R = \frac{PV}{nT} = \frac{(1 \text{ atm}) (22.42 \text{ L})}{(1 \text{ mol})(273.15 \text{ K})} = 0.08208 \frac{\text{atm L}}{\text{mol K}}$$

Since density is mass/volume, we convert mol to mass:

Last sig. fig. (uncertain) a bit different from the standard value (it's normal)

© 2020 Arno Papaz

46

#### **Example:**

Molar Volume of an Ideal Gas

A sample of oxygen gas has a volume of 2.50 L at STP. How many grams of  $O_2$  are present?

Before we find the mass, we need to find the moles

We can use the ideal gas law PV=nR

$$n = \frac{PV}{RT} = \frac{\text{(1 atm) (2.50 L)}}{\text{(0.08206)(273.15 K)}} = 0.11\underline{15} \text{ mol}$$

But it's a lot simpler to use the molar volume at STP:

$$2.50 \text{ L} \times \frac{1 \text{ mol}}{22.42 \text{ L}} = 0.11\underline{1}5 \text{ mol}$$

$$0.11\underline{1}5 \text{ mol} \times \frac{32.00 \text{ g}}{1 \text{ mol}} = 3.57 \text{ g}$$
 m.m.  $O_2 = 32.00 \text{ g/mol}$ 

48

m.m.  $F_2 = 38.00 \text{ g/mol}$ 

Molar Volume of an Ideal Gas

$$d = \frac{mass}{V} = \frac{38.00 \text{ g}}{22.42 \text{ L}} = 1.695 \text{ g/L}$$

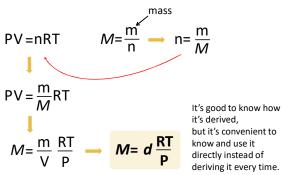

mass = 1 mol  $\times \frac{38.00 \text{ g}}{1 \text{ mol}}$  = 38.00 g

What is the density of  $F_2$  at STP (in g/L)?

At STP, for 1 mol of gas, V=22.42 L

© 2020 Arno Papazyan

© 2020 Amo F

Molar Mass (M) of a Gas

49

# $M = d \frac{RT}{P}$

tells us that gases with higher density have higher molar masses

We can rearrange it to calculate density (d) from molar mass (M):

$$d = M \frac{P}{RT}$$

which tells us that higher molar mass leads to higher density for gases.

© 2020 Arno Papazy

50

#### **Example:**

When 0.960 g of a liquid is vaporized at  $110.^{\circ}$ C and 0.967 atm, the gas occupies a volume of 0.559 L. What is the molar mass of the compound?

We can calculate molar mass of a gas if we know its density at a given P, V, T:  $M = d \frac{RT}{P}$ 

All of the liquid (0.960 g) became gas, occupying 0.559 L d = (0.960 g)/(0.559 L) = 1.71/2 g/L

$$M = d \frac{RT}{P} = (1.7\underline{1}7) \frac{(0.08206)(110.+273)}{(0.967)} = 55.8 \text{ g/mol}$$

Check the units to make sure they cancel and give g/mol

© 2020 Amo Pap

51

Molar Mass (M) of a Ga

Same Example; alternative (and better) solution:

When 0.960 g of a liquid is vaporized at  $110.^{\circ}$ C and 0.967 atm, the gas occupies a volume of 0.559 L. What is the molar mass of the compound?

Given T, P, V, we can calculate n from PV=nRT:

$$n = \frac{PV}{RT} = \frac{(0.967)(0.559)}{(0.08206)(110.+273)} = 0.0172 \text{ mol}$$

Mass, m, of the gas (same as in liquid form) is 0.960 g Molar mass can be calculated from "mass per moles" of a given sample:

$$M = \frac{\text{m}}{\text{n}} = \frac{0.960 \text{ g}}{0.0172 \text{ mol}} = 55.8 \text{ g/mol}$$

Here we bypassed density in calculating the molar mass

© 2020 Arno Papaz

52

#### **Partial Pressures**

Partial Pressure of an ideal gas:

> The pressure it would exert if it were alone

For a mixture of ideal gases in a container,

$$P_{Total} = P_1 + P_2 + P_3 + \dots$$

The total pressure exerted is the <u>sum of the pressures</u> that each gas would exert if it were <u>alone</u>.

- Remember that ideal gas particles don't interact, so they are "unaware" of other gases in the same container
- So the presence of another gas has no effect on what pressure a gas would generate by itself. The pressures simply add up.

pazyan

54

Gas 1 alone
P<sub>1</sub>

Gas 2 alone
P<sub>2</sub>

P = P<sub>1</sub> + P<sub>2</sub>

RD-ryspe latting # Hyten fluxust.

#### **Example:**

Partial Pressures

 $27.4\,L$  of oxygen gas at  $25.0^{\circ}\text{C}$  and  $1.30\,\text{atm},$  and  $8.50\,L$  of helium gas at 25.0°C and 2.00 atm were pumped into a tank with a volume of  $5.81\,L$  at  $25\,^{\circ}\text{C}.$  Calculate the partial pressures of oxygen and helium in the tank, as well as the total pressure.

Both gases go from their original container to the same new tank (new V). We will think about them separately.

Each gas preserves its number of moles, and temperature remains the same at 25.0°C. This means constant **n** and **T**.

At constant **n** and **T**, we have **P** and **V** changing, following Boyle's Law:  $P_1 V_1 = P_2 V_2$ 

For  $O_2$ :  $(1.30)(27.4) = P_2(5.81)$  $P_2 = 6.13 \text{ atm} = P_0$  $P_2 = 2.93 \text{ atm} = P_{He}$ For He:  $(2.00)(8.50) = P_2(5.81)$ 

 $P_{total} = P_{0.} + P_{He} = 6.13 + 2.93 = 9.06$  atm

55

Partial Pressures

#### **Mole Fractions**

mole fraction of A:

$$x_A = \frac{n_A}{n_{total}}$$

Mole fraction is particularly useful with partial pressures

$$P_A = x_A P_{total}$$
  $x_A = \frac{P_A}{P_{total}}$ 

Mole fractions are like "pressure fractions"

$$x_A + x_B + x_C + \cdots = 1$$

$$P_A + P_B + P_C + \cdots = P_{total}$$

56

Partial Pressures: Mole Fraction

#### **Example**

The partial pressures of CH<sub>4</sub>, N<sub>2</sub>, and O<sub>2</sub> in a sample of gas were found to be 135 mmHg, 508 mmHg, and 571 mmHg, respectively. Calculate the mole fraction of nitrogen.

Mole fractions are also like "pressure fractions"

$$X_{N_2} = \frac{P_{N_2}}{P_{total}}$$

 $P_{total} = P_{CH_4} + P_{N_2} + P_{O_2} = 135+508+571 = 1214 \text{ mmHg}$  $x_{N_2} = \frac{508 \text{ mmHg}}{1214 \text{ mmHg}} = 0.418$ 

57

#### **Kinetic Molecular Theory**

So far we have considered "what happens" (Gas Laws) but not the "why" or the "how" of it.

Natural laws tell us what should happen, but don't explain the "mechanics" behind that.

A theory explains why the law exists.

Kinetic Molecular **Theory** explains the ideal gas laws.

58

## **Postulates of the Kinetic Molecular Theory**

Basic assumptions

1. The particles are so small compared with the distances between them that the volume of the particles can be assumed to be negligible.

In other words:

#### Particles have no volume

Entire gas volume is the empty space between particles

No volume contributed by particles themselves

#### **Postulates of the Kinetic Molecular Theory**

2. The particles are in constant motion and their collisions with the container walls are the origin of the pressure exerted by the gas.

Not so much an "assumption".

More of an observation that the collisions are the only source to apply a force on the container walls.

60

## **Postulates of the Kinetic Molecular Theory**

3. The particles exert no forces on each other Importantly:

#### Particles don't attract each other

What about repelling each other? Well, not that either, but in any case intermolecular forces are always attractive except during collisions

They can bounce off each other elastically, but mathematically it's the same as passing through each other

61

#### What makes an ideal gas "ideal"?

Two of the postulates. Rephrased, we have:

"Particles have no volume"

"No intermolecular forces"

63

# Why "Root Mean Square Velocity"? — instead of ordinary average?

We just show here  $u_{\rm rms}$  (and not the ordinary average of velocity) is the important one. No need to memorize anything here, or worry if you don't fully follow.

 $T \propto \text{(average kinetic energy)} \quad u = \text{velocity of particles}$  (average kinetic energy) =  $\frac{1}{2}\text{m}(u_{-}^2)_{av}$ 

 $T \propto (u^2)_{av}$  $T \propto (u_{rms})^2$   $u_{rms} = \sqrt{(u^2)_{av}}$ 

average of the square (of u) is related to the temperature, not the "regular" average of u (they are somewhat different)

 $\sqrt{T} \propto u_{\rm rms}$ 

 $u_{rms} \propto \sqrt{T}$ 

65

The full relationship turns out to be:  $u_{rms} =$ 

 $u_{rms} = \sqrt{\frac{3RT}{M}}$ 

#### **Postulates of the Kinetic Molecular Theory**

4. The average kinetic energy of the gas particles is directly proportional to the Kelvin temperature of the gas.

Basically the <u>definition</u> of Kelvin temperature scale, rather than an "assumption".

62

#### **Root Mean Square Velocity**

A kind of  $\mbox{\bf average}$   $\mbox{\bf velocity}$  useful in kinetic molecular theory

"Square root of the average of the squares of the particle velocities"

$$u_{rms} = \sqrt{\frac{3RT}{M}}$$

R = 8.3145 J/K·mol

(gas constant **expressed in SI units)**J = joule = kg·m<sup>2</sup>/s<sup>2</sup> (SI energy unit)

T = temperature of gas (in K)

M = molar mass in kilograms (kg/mol)
 (kg is the SI unit for mass)

Resultant units are in m/s

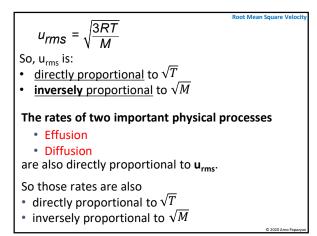

© 2020 Arno Papazya

64

Quick reminder on algebra

$$\sqrt{\frac{3RT}{M}} = \frac{\sqrt{3}\sqrt{R}\sqrt{T}}{\sqrt{M}} = \sqrt{3R} \frac{\sqrt{T}}{\sqrt{M}} = \sqrt{3R} \sqrt{T} \frac{1}{\sqrt{M}}$$

10/11/2021

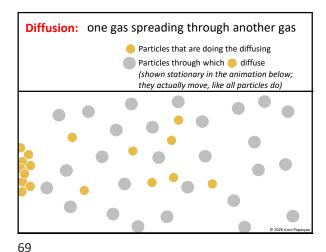

Effusion: passage of a gas through a tiny orifice into an empty chamber (vacuum).

Pinhole

Pinhole

Rate of effusion measures the speed at which the gas is transferred into the chamber.

67

**Graham's Law** 

- Applies to both effusion & diffusion rates
- · Exact for ideal gases
- · Approximate for non-ideal gases

Since rate is directly proportional to  $u_{rms} = \sqrt{\frac{3RT}{M}}$  Rate is directly proportional to  $\frac{1}{\sqrt{M}}$ 

Rate is **inversely** proportional to  $\sqrt{M}$ 

$$\frac{\left(u_{\text{rms}}\right)_{\text{Gas 1}}}{\left(u_{\text{rms}}\right)_{\text{Gas 2}}} = \boxed{\frac{\text{Rate for Gas } \underline{1}}{\text{Rate for Gas } \underline{2}}} = \frac{\sqrt{M_{\underline{2}}}}{\sqrt{M_{\underline{1}}}}$$

70

Caution!

Rate is inversely proportional to time

When comparing the time it takes for gases to diffuse a certain distance or a certain amount of gas to effuse through a pinhole:

Time for gas  $1 - \sqrt{M_1}$ Note how it's different from the ratio of rates

For examples and practice questions involving effusion and diffusion problems, please use the "Practice Questions" and "Suggested end-of-chapter Questions" posted under the resource page of this chapter at papazyan.org

#### Real Gases (as opposed to "ideal" gases)

- An ideal gas is a very useful but a theoretical concept.
   No gas exactly follows the ideal gas law.
- · Gases deviate from ideal gas law when
  - the molar density n/V is high i.e. "too many" particles in a given volume

When the molar density is high, the average distance between particles is small enough, so that:

- · Attractive forces become significant
- Volume of gas particles (assumed zero for ideal gas)
   become a significant fraction of gas volume

73

74

Effect of particle volume on the volume of real gases

The volume of a gas is the volume of the particles plus the volume between particles.

But for an "ideal gas", V<sub>particles</sub> = 0

$$V = V_{\text{between particles}}$$
  $V_{\text{ideal}} = V_{\text{between particles}}$ 

The volume V in the ideal gas law actually corresponds to the volume between particles.

$$PV_{\frac{\text{between particles}}{\text{particles}}} = nRT$$

75

Effect of particle volume on the volume of real gases

Note that we can use a modified ideal gas law if we subtract the volume of particles from the real gas volume

$$P \underbrace{(V-V_{particles})}_{V_{ideal}} = n R T$$

But real gas particles have some volume:  $V_{particles} > 0$ Real gas volume  $V_{real} = V_{ideal} + V_{particles}$ Vereal  $V_{real} > V_{ideal}$ Particles

Volume between particles

Higher pressures and lower temperatures lead to

Even though we are talking about deviating from the ideal

high density. After all, to get to high density, we start from low density (where ideal gas law applies), and PV=nRT can

gas law, we can still use its guidance about when we get

tell us which direction takes us to higher density.

More deviation from

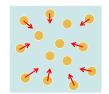

ideal gas law

deviation from the ideal gas law

76

Effect of inter-particle attractions on real gases

In a real gas, attractions between particles pull them away from container walls

We know qualitatively: Inter-particle attractive forces

 $P_{real} < P_{ideal}$ 

decrease real gas pressure compared with ideal gas

78

Real Gas

### For a **real gas**:

- The actual <u>observed volume is larger</u> than the volume expected for an ideal gas due to the volume of the gas particles themselves, which is a "dead" volume into which other gas particles cannot travel.
- The actual <u>observed pressure is lower</u> than the pressure expected for an ideal gas due to the intermolecular attractions that occur in real gases.
